

8. SNMP description

All version 4 EtherMPX devices provide a separate RJ45 connector at the rear side, marked as "MGMT". This is an Ethernet interface dedicated for management purposes over SNMP protocol. At the moment it utilizes only SNMP v1, but this will be enriched in future versions / upgrades.

The supported SNMP PDUs are shown below:

- GetRequest
- SetRequest
- GetNextRequest
- Response
- Trap

The EtherMPX MIB file is the same for Encoder and Decoder. The file contains 50 variables, which some are specific for Encoder devices, some are specific for Decoder devices, and some are valid for both device types.

If you try to issue an SNMP command that is not supported from the specific device type, you will get an error response.

Further down on the document, the whole structure of the MIB file is explained. Since there are no tables in the MIB file, multi-variable commands are not supported; i.e. you cannot issue a GetRequest with 2 (or more) variables in the same request. Instead, a series of GetRequest or GetNextRequest commands can be issued.

SNMP TRAP

EtherMPX issues a TRAP PDU every time the Silence Detector is activated.

• Defaults & Limitations:

- The default read-only community string is **sigmacom**
The default read-write community string is **ethermpx**

 **CAUTION!** You can change the community strings to your choice but they must be of fixed length 8 characters (no more & no less).

- Default IP address of the MGMT port is 192.168.1.16/24
- Variable "sysDeviceName" is used for the unique name you give to the device and it must be of fixed length 16 characters (no more & no less). This name is displayed in the LCD screen of the device.

- **SNMP integration:**

There are 2 ways of integrating an EtherMPX device in your third party SNMP management software. Either load the MIB file that came along with this documentation, or configure the OIDs manually like the example below. If you are configuring the OIDs manually, you can copy-paste them from MIB file but **don't forget to add .0** at the end of each one.

⚠ **Example:**

MIB file: **1.3.6.1.4.1.44467.1.4**
Custom OID: **1.3.6.1.4.1.44467.1.4.0**

The screenshot shows the configuration interface for a 'Sensor SNMP Custom' in PRTG. At the top, there are navigation tabs: Overview, Live Data, 2 days, 30 days, 365 days, Historic Data, Log, Settings, Notifications, and Channels. Below the tabs is a warning box with the following text:

- It might not work to query data from a probe device via SNMP (querying localhost, 127.0.0.1, or ::1). Add this device to PRTG with the IP address that it has in your network and create the SNMP sensor on this device instead.
- Knowledge Base: How do I find out what OID I need to use for a custom sensor?
- For a general introduction to the technology behind SNMP, please see the manual section **Monitoring via SNMP**.

Below the warning box is the 'BASIC SENSOR SETTINGS' section:

- Sensor Name:
- Parent Tags:
- Tags:
- Priority:

Below that is the 'OID VALUES' section:

- OID Value:
- Unit String:

At the bottom, there are 'Save' and 'Cancel' buttons.

To prevent misconfiguration of MGMT network settings, and hence losing contact with the device, a 2 step process has been implemented.

Variables **snmpAgentMask**, **snmpAgentGW**, **snmpAgentIP**, **snmpAgentDNS** are read-only.

If you need to change them, you must first change variables **snmpNewAgentMask**, **snmpNewAgentGW**, **snmpNewAgentIP**, and **snmpNewAgentDNS**. After you verify that everything is correct, then you must set the **snmpSetSettings** variable to **1**.

This will cause active variables to be overwritten with the “new” values and the MGMT engine of EtherMPX will reset for 25 seconds. This will not affect the audio part. After 25 sec you can connect to the new MGMT IP.
